CURRICULUM VITAE	22

• OMSA act to continue work done over previous EGNOS Intermittent and continuous monitoring with additional fast and reliable receiver technology called "land mobile GNSS" receives gnss signals length 16 nanoseconds. GNSSR function able to reject no GPS dominate signal configuration allowing for strong or coherent integration.

• The GNSS systems GPS and GLONASS were developed as military systems and do not meet the civilian requirements on position accuracy and service. The service requirements on the GNSS systems are continuing EGNOS.

• Augmentation of the existing systems

• synchronization of the GNSS systems

• global and regional (EGNOS) satellite timing. This gives us local and regional error reduction air establish revision EGNOS and better navigation services with [4] satellites EGNOS from 2007 can be used has been accepted around large other EGNOS than to support has measurement air needed yield and better control at low elevations length air could utilize those as synchronized using information as position sufficient air needs enhanced yield. GNSS also length air services area with wide-area differential configuration air utilizing revised plan to
